

Task – 05

Part A – Case Study

Choose one of the following cybercrime types: Phishing, UPI/Online Payment Fraud, Identity Theft, Cyberbullying, or Ransomware.

Phishing is a common type of cybercrime in which attackers try to steal sensitive information such as passwords, bank details, or personal data by pretending to be a trusted entity. This is usually done through fake emails, messages, or websites that look legitimate.

A typical phishing attack begins when a user receives an email or message that appears to be from a bank, online service, or official organization. The message often creates urgency, such as asking the user to verify their account or update payment details.

It includes a link that redirects the user to a fake website designed to look identical to the original one. When the user enters their login credentials or financial information, it is captured by the attacker.

Students and individuals who are not aware of such scams are often the primary targets. The consequences can be serious, including financial loss, identity theft, and unauthorized access to personal accounts.

Phishing attacks are increasing rapidly, making it important for individuals to stay aware and cautious while using digital platforms.
